# SLqPCR: Functions for analysis of real-time quantitative PCR data at SIRS-Lab GmbH

Dr. Matthias Kohl SIRS-Lab GmbH (Jena, Germany)

October 27, 2021

#### Contents

1	Introduction	1
2	Selection of most stable reference/housekeeping genes	1
3	Normalization by geometric averaging	6

#### 1 Introduction

The package "SLqPCR" was designed for the analysis of real-time quantitative RT-PCR data. In this short vignette we describe and demonstrate the available functions.

### 2 Selection of most stable reference/housekeeping genes

We describe the selection of the best (most stable) reference/housekeeping genes using method and data set of Vandesompele et al (2002) [1] (in the sequel: Vand02). We load library and data

- > library(SLqPCR)
  > data(vandesompele)
- > str(vandesompele)

```
'data.frame': 85 obs. of 10 variables: $ ACTB : num 0.0425 0.0192 0.1631 0.5726 0.037 ...
```

```

```

We start by ranking the selected reference/housekeeping genes. The function selectHK-genes proceeds stepwise; confer Section "Materials and methods" in Vand02. That is, the gene stability measure M of all candidate genes is computed and the gene with the highest M value is excluded. Then, the gene stability measure M for the remaining gene is calculated and so on. This procedure is repeated until two respectively minnrhk is reached.

```
> tissue <- as.factor(c(rep("BM", 9), rep("POOL", 9), rep("FIB", 20), rep("LEU", 13), rep("
> res.BM <- selectHKgenes(vandesompele[tissue == "BM",], method = "Vandesompele", geneSymbo

- (b) In praxis the selection of reference/housekeeping genes may require an additional step which is the computation of relative quantities via relQuantPCR; e.g.
  - > exa1 <- apply(vandesompele[tissue == "BM",], 2, relQuantPCR, E = 2)

We plot the average expression stability M for each cell type (cf. Figure 2 in Vand02).

```
> library(RColorBrewer)
> mypalette <- brewer.pal(5, "Set1")
> matplot(cbind(res.BM$meanM, res.POOL$meanM, res.FIB$meanM, res.LEU$meanM, res.NB$meanM),
> axis(1, at = 1:9, labels = as.character(10:2))
> axis(2, at = seq(0.2, 1.2, by = 0.2), labels = as.character(seq(0.2, 1.2, by = 0.2)))
> box()
> abline(h = seq(0.2, 1.2, by = 0.2), lty = 2, lwd = 1, col = "grey")
> legend("topright", legend = c("BM", "POOL", "FIB", "LEU", "NB"), fill = mypalette)
```

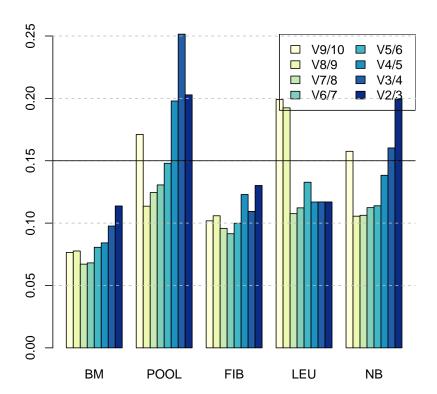

#### Gene stability measure

Second, we plot the pairwise variation for each cell type (cf. Figure 3 (a) in Vand02)

- > mypalette <- brewer.pal(8, "YlGnBu")</pre>
- > barplot(cbind(res.BM\$variation, res.POOL\$variation, res.FIB\$variation, res.LEU\$variation,
- > legend("topright", legend = c("V9/10", "V8/9", "V7/8", "V6/7", "V5/6", "V4/5", "V3/4", "V

```
> abline(h = seq(0.05, 0.25, by = 0.05), lty = 2, col = "grey") > abline(h = 0.15, lty = 1, col = "black")
```

Remark 2: Vand02 recommend a cut-off value of 0.15 for the pairwise variation. Below this bound the inclusion of an additional housekeeping gene is not required.

## 3 Normalization by geometric averaging

To normalize your data by geometric averaging of multiple reference/housekeeping genes you can proceed as follows

- > data(SLqPCRdata)
- > SLqPCRdata
